

THE PARKES CATALOGUE OF RADIO SOURCES

DECLINATION ZONE $+20^\circ$ TO $+27^\circ$

By A. J. SHIMMINS* and G. A. DAY*

[Manuscript received December 4, 1967]

Summary

This paper gives details of 397 radio sources between declinations $+20^\circ$ and $+27^\circ$ which were compiled from a finding survey made at 635 MHz with the 210 ft reflector at the Australian National Radio Astronomy Observatory, Parkes, N.S.W.

The survey covers an area of 0.703 steradian but is incomplete in two regions within $\pm 10^\circ$ of the galactic equator. Additional measurements of flux densities and positions were made at 1410 and 2650 MHz. Some discussions on spectra, source counts, and source identifications are included, and a comparison is made between this survey and other published catalogues covering the same region.

I. INTRODUCTION

This paper is the fifth section of a survey for radio sources being made with the 210 ft radio telescope at the Australian National Radio Astronomy Observatory, Parkes, N.S.W. The earlier parts of the survey have already been published and cover the declination zones 0° to $+20^\circ$ (Day *et al.* 1966), 0° to -20° (Shimmins *et al.* 1966), -20° to -60° (Bolton, Gardner, and Mackey 1964), and -60° to -90° (Price and Milne 1965). The present paper covers the remaining declination zone that is visible with the Parkes telescope, $+20^\circ$ to $+27^\circ$, and is complete except for two areas within $\pm 10^\circ$ of the galactic equator. The catalogue contains 397 sources within 0.703 steradian, 341 of these sources being outside the region $\pm 10^\circ$ of the galactic equator (effective area 0.606 steradian). The catalogue is thought to be substantially complete down to a flux density of 1.5 f.u.[†] at 635 MHz outside the galactic plane region but contains some weaker sources down to 0.8 f.u.

The observations differ from those of the earlier sections of the catalogue in that the finding survey was done at a frequency of 635 MHz. Positions and flux densities were subsequently measured at 1410 and 2650 MHz.

The estimated r.m.s. errors in position and the date of measurement are given for each source in the catalogue. For most of the sources the positions stated have an r.m.s. error of less than 1'.0 arc in each coordinate. A few of the weaker sources have errors of up to 2'.0 in each coordinate. Spectra and source counts at the three frequencies are discussed and a comparison is made between the results of this survey and the Cambridge 4C catalogue (Pilkington and Scott 1965) and the California Institute of Technology CTD list (Kellerman and Read 1965) for the regions of overlap. The results of an examination by J. G. Bolton of the source positions on the Palomar Sky Survey prints have been included.

* Division of Radiophysics, CSIRO, Box 76, P.O. Epping, N.S.W. 2121.

† 1 flux unit = 10^{-26} W m⁻² Hz⁻¹.

II. OBSERVATIONS AND EQUIPMENT

The observational procedures for this survey were similar to those for the previous surveys; they are given in detail in the first part of the catalogue (Bolton, Gardner, and Mackey 1964). The major difference is that the finding survey was carried out at 635 MHz rather than at 408 MHz. A degenerate parametric receiver with a 10 MHz bandwidth and a system temperature of 215°K was used. With a 2 sec time constant the peak-to-peak noise fluctuation was 0·33 degK, which corresponds to 0·50 f.u. At 635 MHz the telescope has a beamwidth of 30'·6 arc, and the flux limit was set by confusion between adjacent sources and by background irregularities rather than by the system noise.

The observations at 635 MHz consisted of a series of scans at 2·5 deg/min between declinations +20° and +27°. Adjacent scans were made at intervals of 2^m of right ascension. From these records 738 objects were selected down to a flux density of 0·7 f.u. at 635 MHz. Of these, approximately 400 of the strongest objects were subsequently selected for position and flux density measurement at 1410 and 2650 MHz. Most of the sources in this catalogue are stronger than 1 f.u. at 635 MHz.

All strong sources, with flux density greater than 3 f.u. at 635 MHz (or 0·8 f.u. at 2650 MHz), have been accurately positioned at 2650 MHz as part of a separate programme of accurate position measurement (Shimmins 1968). For the weaker sources some were positioned at 2650 MHz and some at 1410 MHz, the particular frequency being indicated in the catalogue (Table 2, column 13).

TABLE 1
DATES OF OBSERVATIONS AND POSITIONAL ERRORS

Reference	Observation Period	Frequency (MHz)	Estimated R.M.S. Error	Remarks
T6	July 29–30, 1965	2650	15"	Near transit
T10	Oct. 8–11, 1966	2650	16"	Near transit
T11A	Feb. 1–2, 1967	2650	18"	Near transit
T11B	Feb. 3–4, 1967	2650	30"	
T12A	June 22–27, 1967	2650	30"	
T20	Feb. 24–26, 1967	1410	1'–2'	
T21	May 15, 1967	1410	1'–2'	
T22	Sept. 14–15, 1967	1410	1'–2'	

III. SOURCE POSITION ERRORS

The position errors depend on the flux density of the source and the frequency at which its position was measured. All the strong sources were measured at 2650 MHz either near transit across the northern meridian, with an average r.m.s. positional error of 16" arc in each coordinate, or off the meridian, in which case the r.m.s. error is 30" arc. The positions of the weakest sources were measured at 1410 MHz and have an r.m.s. error of 1'·0 arc in each coordinate for sources stronger than 0·5 f.u. at 1410 MHz and 2'·0 arc for those few sources weaker than 0·5 f.u. Table 1 shows

the various observing sessions during which positions were measured, and the estimated r.m.s. error for each. For each source in the catalogue, the period of observation is indicated (Table 2, column 13).

IV. NOTES ON THE CATALOGUE

Table 2 contains details of the 397 sources in the declination zone $+20^\circ$ to $+27^\circ$:

Column 1. Parkes catalogue number derived from hours and minutes of right ascension and sign and degrees of declination.

Columns 2 and 3. Mean position for epoch 1950·0. For a discussion of position errors see Section III.

Columns 4 and 5. Annual precession in right ascension (seconds of time) and declination (seconds of arc).

Columns 6, 7, 8, and 9. Flux densities in flux units at frequencies of 178, 635, 1410, and 2650 MHz. The values at 178 MHz are from the 4C catalogue (Pilkington and Scott 1965). Where the flux density errors are thought to be significantly greater than those quoted in Table 3, Section V(b), the flux density has been placed in parentheses. For a discussion on the determination of flux densities, see Section V.

Columns 10 and 11. Values of the mean spectral index, flux density at 400 MHz, and estimated r.m.s. errors. C indicates a departure from a power law spectrum (see Section VI).

Column 12. Identification and remarks. The numerals I-IV refer to the classification of the optical field, on the Palomar Sky Survey prints, within a rectangle $\pm 1' \cdot 0$ from the position of the source (see Section VII). Where an optical identification has been made the following abbreviations apply: QSO, quasi-stellar object; QSO?, possible quasi-stellar object; E, elliptical galaxy; D, spherical galaxy with diffuse envelope; N, compact blue galaxy; S, spiral galaxy; DB, dumb-bell galaxy; M, estimated photographic magnitude; GAL, galaxy for which the type has not been determined. Other abbreviations used are: EXT, source appears extended, as indicated by beam broadening at 2650 MHz; CONF, confused, either with the background or with the source stated.

Column 13. Reference to period of observation during which position and flux density were measured (see Table 1).

Columns 14 and 15. New galactic coordinates.

Columns 16 and 17. Catalogue numbers as given by Pilkington and Scott (1965, 4C catalogue), Kellerman and Read (1965, CTD list), and Pauliny-Toth, Wade, and Heeschen (1966, NRAO); NPC = not previously catalogued. Parentheses around a catalogue number indicate that the source has been resolved at higher frequencies or that there is some doubt that the source and the Parkes catalogue source are identical.

V. DETERMINATION OF FLUX DENSITIES

(a) Measurement of Flux Densities

Flux densities at 635 MHz were obtained by measurement of the amplitude of the source on the finding survey. A correction was applied to allow for the difference between the measured right ascension of the source and that of the nearest survey scan. In a number of cases where the flux density was in doubt, several additional scans at 635 MHz were taken through the source. Source amplitude was expressed in terms of a noise calibration, which was injected at frequent intervals during the survey. The value of the calibration signal was obtained from measurements of Hydra A, which was taken as 90.0 f.u. at 635 MHz.

Where the sources were positioned at 2650 MHz as part of the accurate position programme (Shimmins 1968) the mean flux density measured at position angles 0° and 90° was used, thus eliminating errors due to polarization. These values were calibrated by assuming a flux density of 23.5 f.u. for Hydra A. Where the source was positioned at 2650 MHz, the flux density at 1410 MHz was obtained by on-off source measurements, using the 2650 MHz positions. Amplitudes were measured against a noise calibration, the value of which was obtained by measurements of Hydra A, for which a flux density of 42.0 f.u. at 1410 MHz was adopted.

Where the sources were positioned at 1410 MHz the 1410 MHz flux densities were obtained from the amplitudes of the positioning scans and the 2650 MHz flux densities from subsequent on-off source measurements. Flux densities at 178 MHz are from the 4C catalogue.

TABLE 3
ESTIMATED ERRORS IN FLUX DENSITY MEASUREMENTS

Source of Error	R.M.S. Error at a Frequency of:		
	2650 MHz	1410 MHz	635 MHz
Variation in calibration signal	8%	8%	8%
Angular extent of source	2%	1%	—
Noise fluctuation	0.05 f.u.	0.1 f.u.	0.2 f.u.
Confusion effects	0.03 f.u.	0.1 f.u.	0.4 f.u.
Estimated total r.m.s. error	8% ± 0.06 f.u.	8% ± 0.14 f.u.	8% ± 0.5 f.u.

(b) Errors in Flux Densities

Table 3 gives estimates of the average errors that apply to flux density measurements. These estimates allow for variations in the calibration signal, possible source extension, noise fluctuation, and confusion effects. Where the error in a flux density is thought to be significantly greater than average, the flux density given in Table 2 is in parentheses.

VI. SPECTRA OF SOURCES

The spectral index α is defined by the expression $S = kf^{-\alpha}$, where S is the flux density measured at frequency f and k is a constant. Excluding values outside the average error range, where a source had flux density measurements at two or more frequencies (including 178 MHz) the values were used to determine the straight line

$$\log S = -\alpha \log f + \text{constant}.$$

Each flux density was weighted by the inverse square of its r.m.s. error as given in Table 3. The values with more than average errors were considered as if they had double these errors.

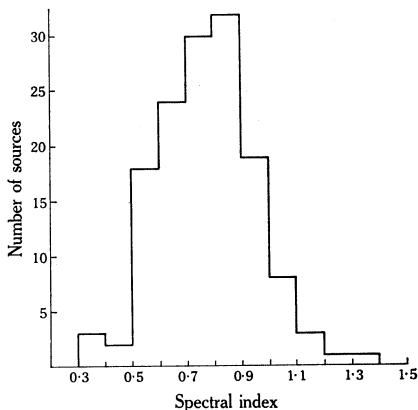

Fig. 1.—Histogram of spectral indices of 141 sources with well-defined spectra. The mean spectral index is 0.83 with a standard deviation of 0.19.

The spectral index and estimated flux density at 400 MHz are given in columns 10 and 11 of Table 2 with the r.m.s. errors determined from those quoted for flux densities. The r.m.s. error corresponding to the goodness of fit was calculated for each source, and where this was significantly greater than the expected error, indicating a departure from a power law spectrum, a C is given in column 10. As can be seen from Table 2, the errors in flux densities, particularly for the weaker sources, are high and this results in large probable errors in the determination of spectral indices.

For a sample of 141 sources for which the spectral indices are well defined with an error of ± 0.2 or less, a histogram of the distribution of spectral indices is shown in Figure 1. The mean spectral index is 0.83 with a standard deviation of 0.19.

Of the 323 sources outside $\pm 10^\circ$ from the galactic equator for which a spectral index is available, approximately 38 (i.e. 12%) have spectral indices of 0.6 or less and only 5% have spectral indices of 0.5 or less.

VII. IDENTIFICATIONS

The optical classifications given in column 12 of Table 2 refer to the field within a rectangle $\pm 1^\circ$ from the position of the source. The fields are defined:

class I, the error rectangle includes one galaxy or more brighter than $m_{pg} = 17$; class II, the error rectangle includes one galaxy or more brighter than $m_{pg} = 19.5$ but fainter than $m_{pg} = 17$; class III, the error rectangle includes no galaxies above the plate limit; class IV, the field is heavily obscured; class HII, the field contains an emission nebula.

J. G. Bolton and Jeannette Merkelijs have examined the fields of all sources, using the 48 in. Palomar Sky Survey prints, and the results are being published in separate papers. Only the results for the strong sources have been included in column 12; these have been taken from Merkelijs, Shimmins, and Bolton (1968).

VIII. SOURCE COUNTS

The present survey gives the flux densities of 341 sources in an area of 0.606 steradian, i.e. excluding the region within 10° of the galactic equator. Figure 2 shows a plot of N , the number of sources per steradian of flux density equal to or greater than S , versus the flux density S , using logarithmic scales.

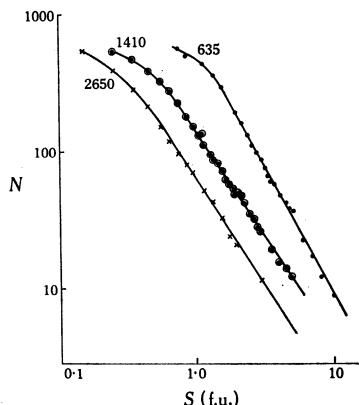

Fig. 2.—Relationship between flux density S and the number N of sources per steradian above a given level of flux density for frequencies of 2650, 1410, and 635 MHz.

The slopes of the lines for the three frequencies are 1.86 ± 0.10 at 635 MHz, 1.65 ± 0.10 at 1410 MHz, and 1.55 ± 0.10 at 2650 MHz. These slopes are very similar to those obtained for the 0° to $+20^\circ$ section of the Parkes catalogue. Of particular interest is the low slope of the $\log N - \log S$ curve at 2650 MHz. This is consistent with the sources having a small systematic increase in spectral index as they get weaker. It is not certain whether this increase is real or due to some systematic underestimation of the 2650 MHz flux densities with decreasing flux density.

As determined from the $\log N - \log S$ curves, it appears that the catalogue is substantially complete down to a flux density of 1.5 f.u. at 635 MHz (300 sources per steradian).

The density of sources at 1410 MHz is 139 sources per steradian with a flux density of 1.0 f.u. or stronger.

IX. COMPARISON WITH OTHER CATALOGUES

Two other catalogues that cover the same area of sky are: "A survey of radio sources between declinations $+20^\circ$ and $+40^\circ$ " by Pilkington and Scott (1965), which is part of the Cambridge 4C catalogue, and "A continuum survey for discrete radio sources at 1421 Mc/s" by Kellerman and Read (1965) (known as the CTD list).

(a) Comparison with 4C Catalogue

The 4C survey was carried out at 178 MHz and is complete to 2 f.u. at 178 MHz, with a positional accuracy of $0' \cdot 5$ in right ascension and $3'$ in declination. The 4C catalogue contains 436 sources in the area, of which 313 are in the present catalogue. Most of the 123 4C sources not presented here have been found on the 635 MHz finding survey but have not been positioned, 94 of them being weaker than $0 \cdot 9$ f.u. at 635 MHz (or $2 \cdot 5$ f.u. at 178 MHz).

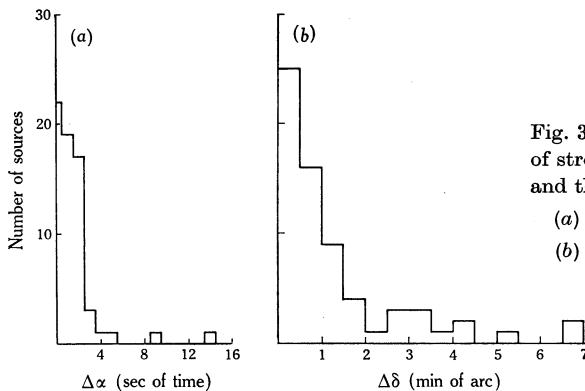

Fig. 3.—A comparison of the positions of strong sources in the present catalogue and those in the 4C catalogue:
 (a) differences in right ascensions $\Delta\alpha$
 (b) differences in declinations $\Delta\delta$

Of particular interest are the 82 sources in the present catalogue that are not in the 4C catalogue. Of these, 20 are close to 4C sources and 12 are within $\pm 10^\circ$ of the galactic plane. These 32 sources can be reasonably explained, but of the remaining 50 sources only 11 have spectra and flux densities at centimetre frequencies such that the expected flux density at 178 MHz would be below the 4C limit. A comparison of the positions given here with those in the 4C catalogue has been made for the stronger sources where the positional accuracy of the present catalogue is better than $30''$ arc in each coordinate. The differences in right ascension and declination are shown in histogram form in Figures 3(a) and 3(b). The agreement in right ascension is less than 3 sec of time, and the declination shows a difference of approximately $1'$ arc.

(b) Comparison with CTD List

The CTD survey was carried out at 1421 MHz and covers the declination range $+23^\circ 50'$ to $+30^\circ 10'$, thus providing a $3^\circ 10'$ overlap zone. The survey is stated to be complete to 1.15 f.u. at 1421 MHz and contains sources of flux density down to 0.5 f.u. at 1421 MHz. A comparison has been made between the CTD list and the

present catalogue in the overlap zone, in which there are 63 CTD sources. Five of these sources are not given here; CTD 26, 29, and 138 were not present on the records of the finding survey, and CTD 110 and 113 are within $\pm 10^\circ$ of the galactic plane where the present survey is incomplete. There are 58 sources in the overlap region that are not in the CTD list. Of these, 10 are stronger than 1.0 f.u. at 1410 MHz and might reasonably have been expected in the CTD list, and the others are weaker than 1.0 f.u., where it is known that the CTD list is incomplete. The CTD list gives a source density of 145 ± 18 sources per steradian, at a flux level of 1 f.u., with a $\log N - \log S$ slope of -1.57 ± 0.20 for sources more than 10° from the galactic equator. This compares with the value of 139 ± 15 sources per steradian, with slope -1.60 , obtained in the present survey.

The agreement in position is not inconsistent with the $\pm 12''$ in right ascension and $\pm 5'$ in declination quoted in the CTD list.

X. ACKNOWLEDGMENTS

Thanks are due to the maintenance staff at the Australian National Radio Astronomy Observatory, Parkes, N.S.W., who operated and maintained the 210 ft radio telescope and receiver during the observations.

Table 2 was produced on the CDC computer at the CSIRO Computing Research Section, Sydney. The programme for the computer was compiled by Mrs. Jennifer Ekers.

Thanks are also due to Miss Mary Chapman of the Division of Radiophysics, CSIRO, who carried out the precessions of the measured source positions and also assisted in the preparation of data for source identifications.
