## **Appendix 1.** Background notes on relevant Quaternary climatic and sea-level events.

### *Environmental forcing mechanisms: Quaternary climates and refugia*

On the basis of very limited and poorly dated evidence (e.g. Fairbridge 1964; Jennings 1975), the Last Glacial Maximum (LGM) was thought to be arid, with virtually no summer monsoon regime. This model drove both archaeological and ecological discussions but has to be revisited in the light of more recent work. A more comprehensive understanding of Quaternary paleoclimate events in the monsoon region of north-western Australia has become available over the last few years, specifically development of the proxy record (e.g. Bowler *et al.* 2001; Wyrwoll and Miller 2001) and information on the dynamics of the paleoclimatology (Wyrwoll and Valdes 2003; Wyrwoll *et al.* 2007; McRobie *et al.* 2015; Eroglu *et al.* 2016).

### *Mangrove forests in the context of Late Pleistocene sea-level and climatic fluctuations*

The long-term record of global sea-level changes over Quaternary time scales is based both on proxy deep sea oxygen isotope ( $^{18}\text{O}$ ) events and numerically dated stratigraphic sequences, such as the well known coral reef successions and coastal stratigraphic records more generally – among these being mangrove ecotones (Woodroffe 1990).

In the general discussion of the relationship between mangrove response and sea-level changes, there is the general claim that extensive mangrove development occurs during periods of marine transgression, while less pronounced mangrove stands characterize marine regressions and periods of relative sea-level stability (Grindrod *et al.* 1999).

A conceptual model that captures the response of mangroves to sea-level changes is provided by Soares (2009; also see Ellison 2015), while Krauss *et al.* (2014) outline the details of how mangrove stands accommodate rising sea-levels. Soares (2009) emphasises the importance of the rate of sea-level rise, sediment and sedimentation regimes, regional oceanographic controls and coastal geomorphology. Taking a more focused view, Krauss *et al.* (2014) add climate and atmospheric CO<sub>2</sub> concentrations as relevant considerations.

From ice cores, Monnin *et al.* (2001) inferred a significant increase in atmospheric CO<sub>2</sub> concentration between LGM (~180 ppm) and pre-industrial (280 ppm) periods. Although, a response of mangrove species to CO<sub>2</sub> changes has been demonstrated under controlled conditions (Ellison, 2015), it is not clear how this change could have influenced mangrove forests (see Krauss *et al.* 2014), and available evidence suggests that it is unlikely that Late Quaternary atmospheric CO<sub>2</sub> level changes acted prohibitively on mangrove ecology.

In the geomorphological and paleoecological literature there has been a persistent claim that mangrove changes are driven by climate (for example, Jennings 1975; discussion in Grindrod *et al.* 2002). Most recently, Proske *et al.* (2014) proposed that enhanced summer monsoon rainfall between 7.5 and 4.5 kyr BP, prompted widespread mangrove coverage in the Cambridge Gulf region (the lower Ord River) of north-western Australia (Fig. 1b). However, radiocarbon dating evidence from the South Alligator River in the Northern Territory show that extensive mangrove swamps developed between 6,500 and 7,000 years ago and flourished for about 1000 years (Woodroffe *et al.* 1985); rather than claiming a role for climate, these authors link the growth of these forests to the interaction of sea-level change and sedimentation.

Even so, the role of climate in present-day mangrove ecology is evidenced by the decrease in mangrove diversity with lower temperatures (Ellison 2015) and the reduction in mangrove primary productivity with decreased humidity associated with lower precipitation (Lovelock and Ellison 2007). But the stratigraphic record makes it clear that in the summer monsoon regions of north-western Australia-Indonesia, mangroves occupy an ‘environmental envelope’ that can accommodate the climate changes that characterised this region over Quaternary time scales.

While there is clearly a role for climate in mangrove ecology, the more general claim of climate being a direct driver remains open to doubt. A more certain claim is that over long time scales, mangrove abundance in the monsoon region of Australia-Indonesia is greatly influenced by environmental controls linked to the physical evolution of coasts. Sea-level change and stages in the geomorphological development of coasts in the monsoon region of Australia-Indonesia seem to be the dominant controls of mangrove abundance (Thom 1982; Woodroffe 1990; Grindrod *et al.* 2002). Sea-levels lower than present provided the necessary geomorphological settings, extensive mangrove forests are expected to have fringed the then existing coastal margins – which is exactly what the stratigraphic record indicates.

## **Appendix 2.** Bioregional descriptions (see Fig. 1).

**DAC (Darwin Coast):** Has a mesic monsoon climate (1700 mm rainfall annually) and, like the ARC and TWI, is characterised by gently undulating plains on lateritized Cretaceous sandstones and siltstones mantled by sandy and loamy red and yellow earths and siliceous sands supporting tall open eucalypt forest with a shrub and cane grass understorey. Extensive, diverse floodplains are associated with the lower reaches of the many large river systems, with riparian vegetation fringing the rivers and substantial areas of rainforest. Extensive mangrove forests occur in embayments and river mouths, and fringing the coast.

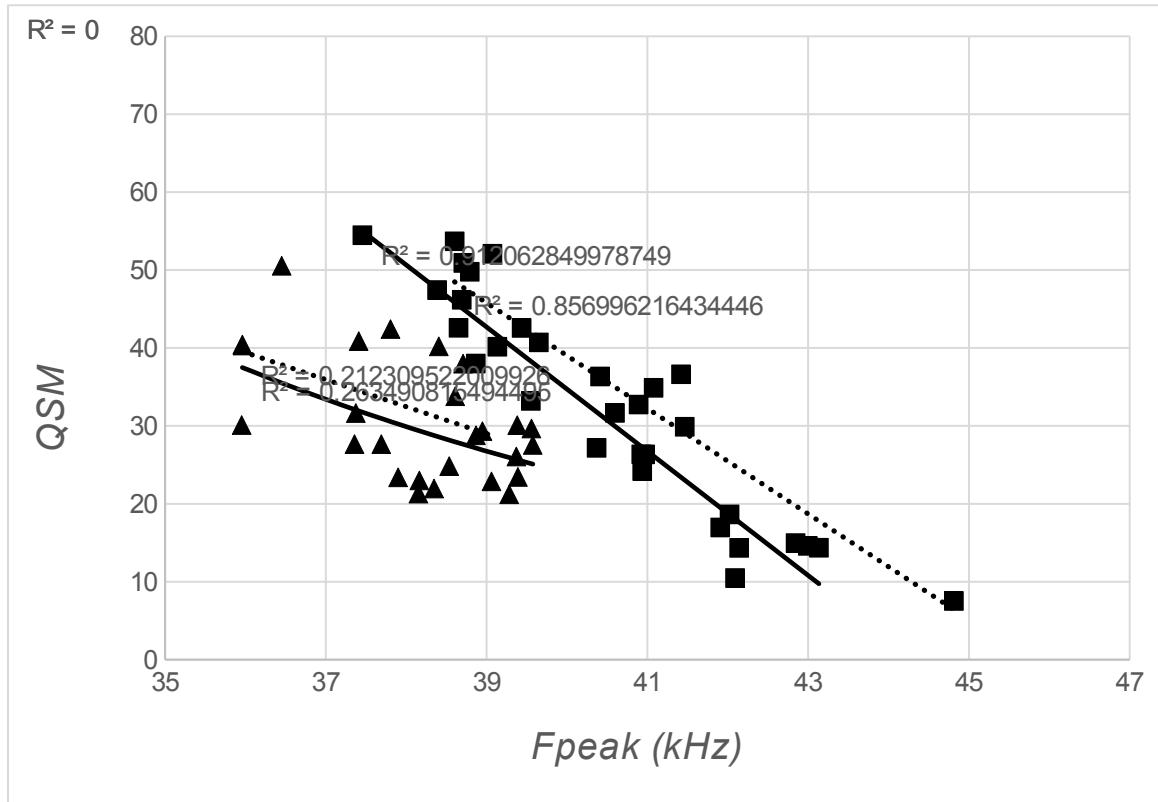

**ARC (Arnhem Coast):** With TWI, the most mesic bioregion in the study area. It includes sub-humid near-coastal as well as upland landscapes that are mainly expressed as coastal plains, gently undulating plains and low plateaux on lateritized Cretaceous sandstones and siltstones, as well as rugged, deeply incised, rocky, plateau surfaces dissected by gorges. The plains separate the uplands from the coast in places; they comprise extensive coastal dune systems, saline flats, wetlands and floodplains. Mangrove forests are common along the coast, particularly in sheltered embayments and estuaries. The wider landscapes of the uplands support grasslands, savannas, tree steppes, woodlands and open forests on: (1) red and yellow earths that mantle the undulating hill-country and broad valleys, and (2) rugged boulder country mainly associated with extensive quartz sandstone strata that are discontinuously mantled by skeletal soils. The uplands are drained by seasonally active, flood dominant river systems with many permanent pools fringed by tall trees that form riparian forests or woodlands.

**GUC (Gulf Coast):** Has a mesic monsoon climate, and receives 700 to 900 mm per annum. Its landscapes are dominated by gently undulating plains of red earths and shallow gravelly sand that support eucalypt woodlands over a tussock grass and spinifex understorey, with large meandering rivers and seasonal coastal swamps. Rugged areas on Proterozoic sandstone and Tertiary sediments occur in some places; coastal areas are not rocky, except on the Pellew Islands. The coastal plains support samphire shrublands and beach dunes. Mangrove forests are extensive along the coast, and fringe river estuaries for up to 10 km inland.

**Appendix 3.** Results of acoustic surveys at sites in CARn (see Appendix 5) and on the Northern Territory coast in August 2019 and June 2021, respectively. Species codes are explained in Table 1.

**Appendix 4.** Distinguishing *Chalinolobus nigrogriseus* (*Cn*, circles), *Scotorepens sanborni* (*Ss*, squares) and *S. greyii* (*Sg*, triangles) in terms of their search mode echolocation pulses sequence averages. Northern Territory data are plotted as solid symbols; Kimberley data are hollow symbols.

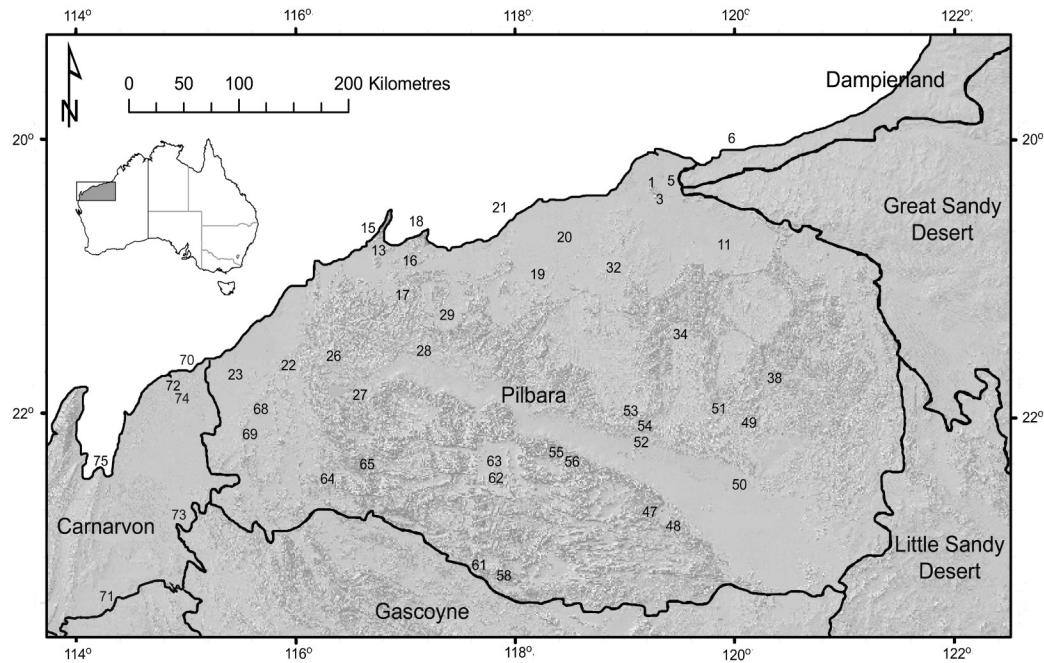

**Appendix 5.** (a) Locations of bat survey sites used in the Kimberley species classification analyses (see Appendix 2). (b) Locations of bat survey sites used in the “PIL+CARn” species classification analyses (see Appendix 3).

**a.**

**b.**

**Appendix 6.** OZCAM (2020), NRmaps and ALA online listings of specimens representing all zoophagous bat species known from coastal bioregions in the Northern Territory, other than those listed in Appendix 7. Certain relevant records from Queensland and Western Australia are also listed. Where feasible, the collection localities (Google Earth WMG) have been confirmed by the original collectors (specifically, by Damian Milne, Terry Reardon and Harry Parnaby).

**Appendix 7.** Identification of tropical Australian *Scotorepens* specimens based on cranial morphometrics (Kitchener *et al.* 1985, 1994), allozyme electrophoresis (Baverstock *et al.* 1987; Kitchener *et al.* 1994), and re-examination of museum specimens in terms of skull shape following McKenzie and Bullen (2012): mastoid angle (S)teep or (N)ot; rostrum (T)ilted or (N)ot. Specimen collection localities (Google Earth WMG) have been updated from information supplied by the original collectors. 'Mapped location' refers to the maps in **KC** (Kitchener and Caputi 1985), **B** (Baverstock *et al.* 1987) and **KA** (Kitchener and Adams 1994).

**Sg: 39/42 cp published**

**Ss: 27/27 cp published**

**Appendix 8.** Habitat specificity of southern Papua New Guinea (PNG) and Irian Jaya populations of taxa that are ecomorphological and phylogenetic counterparts of the four Western Australian mangrove specialists.

Bonaccorso (1998) and IUCN (2020) list southern PNG populations of *S. sanborni* as occupying coastal, lowland sclerophyll forests and rainforests from sea level to 3200 m altitude (although most specimens were recorded below 100 m); *Mormopterus loriae*, the counterpart of *O. cobourgianus*, as restricted to open sclerophyll forest and occurring from sea level to 100 m altitude throughout its range; *Pipistrellus papuanus*, the counterpart of *P. westralis* (see Kitchener *et al.* 1986), as occurring from sea level to 1300 m altitude, where it forages in village, plantation and wooded stream environments. Finally, they list PNG populations of *Nyctophilus microtis*, the counterpart of *N. arnhemensis*, as occurring from sea level to 1450 m altitude, where it has been mist netted in primary and secondary forest and forest clearings.

**Appendix 9.** Habitats each of the study area's bat species was likely to occupy by during the last glacial.

During the period of drier conditions synchronised with the lowered sea levels of the LGM:

- (a) Some bat species refuged in gorge/riparian habitat associated with uplands in or around the Kimberley (*M. macropus*, *N. walkeri* and *V. douglasorum*) and/or Pilbara cratons (*N. daedalus* and, perhaps, *C. morio*). Five others refuged there too, further shielded by their physiologically benign cave roosts (*H. ater*, *H. stenotis*, *M. gigas*, *M. oriana* and *R. aurantia*). The other two Western Australian landward species (*O. lumsdenae* and, *S. greyii*) persisted throughout landward environments of the Kimberley and Pilbara because they are pre-adapted to drier conditions, hence their wide arid, semi-arid and/or mesic geographic ranges elsewhere throughout tropical Australia.
- (b) *O. cobourgianus*, *P. westralis*, *S. sanborni*, as well as the cave-dependent species component, refuged in mangrove forest fringing the exposed edge of the continental shelf, the cave-dependents roosting in barrier reef/limestone karst caves exposed along the shelf-edge and/or the incised drainage canyons (Voris 2006; McCaffrey *et al.* 2020).
- (c) *N. arnhemensis*, *C. nigrogriseus*, *S. saccolaimus* and *V. caurinus* refuged in both (a) and (b). Another five (*N. geoffroyi*, *S. flaviventris*, *C. jobensis*, *C. gouldii* and *A. australis*) are pre-adapted to drier conditions (i.e. their range includes semi-arid and/or arid regions) so persisted throughout landward and mangrove ecosystems, as did *T. georgianus* provided it was within reach of suitable cave roosts to mitigate its energy requirements.
- (d) The arid zone specialists (*T. hilli* and *V. finlaysoni*) may have penetrated further into the Kimberley uplands, like they do today in the more arid Pilbara and northern Carnarvon Basin.
